Abstract

A fundamentally different approach to path integral quantum mechanics in curved space-time is presented, as compared to the standard approaches currently available in the literature. Within the context of scalar particle propagation in a locally curved background, such as described by Fermi or Riemann normal co-ordinates, this approach requires use of a constructed operator to rotate the initial, intermediate, and final position ket vectors onto their respective local tangent spaces, defined at each local time step along some arbitrary classical reference worldline. Local time translation is described using a quantum mechanical representation of Lie transport, that while strictly non-unitary in operator form, nevertheless correctly recovers the free-particle Lagrangian in curved space-time, along with new contributions. This propagator yields the prediction that all probability violating terms due to curvature contribute to a quantum violation of the weak equivalence principle, while the remaining terms that conserve probability also correspondingly satisfy the weak equivalence principle, at least to leading-order in the particle's Compton wavelength. Furthermore, this propagator possesses an overall curvature-dependent and gauge-invariant phase factor that can be interpreted as the gravitational Aharonov-Bohm effect and Berry's phase.

Key words: path integrals, quantum mechanics, curved space-time, weak equivalence principle violation

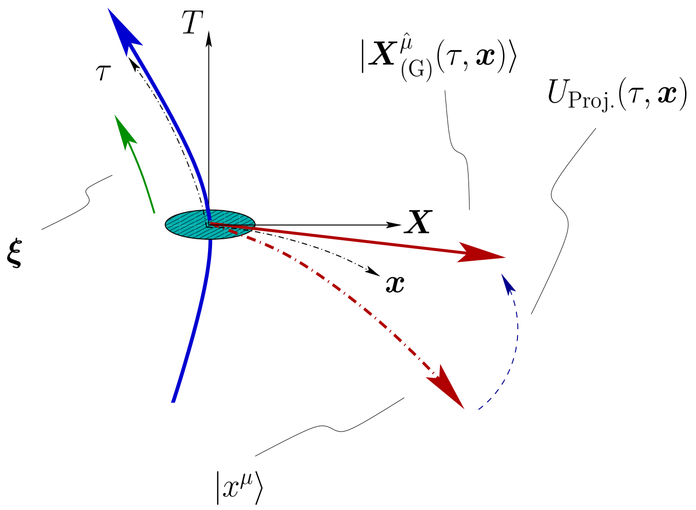
1 Introduction

It is an undeniable fact that the Feynman path integral approach to quantum mechanics [1,2] has made significant contributions towards the present-day understanding of theoretical physics, especially in the study of subatomic particle theory, condensed matter, and statistical mechanics [3]. While as a computational tool within quantum mechanics it is arguably less relevant for physical problems that are much easier to solve via the standard canonical quantization approach, its inherent value comes from the physical insight it provides on the relationship between classical and quantum phenomena within a unified mathematical framework [5]. In terms of a conceptually intuitive view of quantum mechanics as a "sum-over-histories" for all possible *classical worldlines* in space-time, the path integral approach is well-suited for better understanding quantum phenomena in the presence of a classical gravitational background [6], which may lay the groundwork towards finding a self-consistent theory of quantum gravity.

At present, this ultimate goal has remained elusive for over 70 years, in no small part due to the lack of any physical data to provide grounding and direction for building the theory. Nonetheless, it can be argued that many useful theoretically-motivated efforts already exist, including the path integral approach. This is most evident through the pioneering efforts of DeWitt for developing much of the mathematical machinery now used for this avenue of searching for quantum gravity [7]. Within a more modest semiclassical context, such as quantum field theory in curved space-time, many advances have also taken place from applying a path integral approach—which avoids certain conceptual issues related to the loss of a global Poincaré symmetry used to denote the inherent nature of particles—while recovering interesting physical consequences originally obtained by canonical methods.

Notwithstanding the standard approaches to path integral quantum gravity or quantum field theory in curved space-time [3,4,8–11], there are a number of relevant conceptual questions to raise about the precise physical nature of quantum particle propagation in a non-trivial gravitational background. For example, to what extent does the curved space-time manifold have a mathematically smooth structure when applying the path integral approach? Is it possible to effectively perform the sum-over-histories when the intermediate classical paths deviate significantly from a classical geodesic? Is the presence of space-time torsion necessarily required to correctly define the path integral in curved space-time [3,4]? Are the intermediate classical paths required to preserve local causality or should they be free to trace out causality-violating worldlines, including ones that imply propagation into the local past [11]? To what extent can a coarse-grained skeletonized form of the path integral in curved space-time be identified with a truly continuum form in the limit as



T
τ
$|\boldsymbol{X}^{\hat{\mu}}_{(\mathrm{G})}(\tau,\boldsymbol{x})\rangle$
$U_{\mathrm{Proj.}}(\tau,\boldsymbol{x})$
$\boldsymbol{\xi}$
$\boldsymbol{X}$
$\boldsymbol{x}$
$|x^{\mu}\rangle$

Fig. 1. A projection operator $U_{\mathrm{Proj.}}(\tau,\boldsymbol{x})$ is used to transform the position ket vector $|x^{\mu}\rangle$, defined with respect to Fermi or Riemann normal co-ordinates, into $|\boldsymbol{X}^{\hat{\mu}}_{(\mathrm{G})}(\tau,\boldsymbol{x})\rangle = U_{\mathrm{Proj.}}(\tau,\boldsymbol{x})\,|x^{\mu}\rangle$ that exists on a local tangent space defined at τ. Proper time translation of $|\boldsymbol{X}^{\hat{\mu}}_{(\mathrm{G})}(\tau,\boldsymbol{x})\rangle$ is determined according to Lie transport with respect to a vector field $\boldsymbol{\xi}$ that is tangent to the reference worldline.

the finitely chosen time step becomes infinitesimally small? In the absence of physical data, it seems unclear whether any of these questions can be readily answered.

Instead of addressing these questions outright, the approach taken in this Letter is to consider the idea of path integral quantum mechanics for a scalar particle from a fundamentally different perspective, while simultaneously preserving Feynman's original vision to the best extent possible. This is done by formulating the problem in terms of either Fermi or Riemann normal co-ordinates and employing the orthonormal tetrad formalism [12] to relate all quantities with respect to local tangent spaces at successive local time steps. As a result of taking this approach, a number of interesting physical predictions emerge from the scalar particle propagator that are not readily evident in the more standard approaches found in the literature—while still preserving its expected properties in flat space-time. Potentially observable implications also appear for future consideration. Though full computational details of this approach will be forthcoming in a much longer publication [13], it is possible to still outline some of the essential features of this approach. All computations are performed assuming the curvature conventions of Misner, Thorne, and Wheeler [14]. As well, $c = 1$ is assumed throughout.

2 Formalism

The key behind this new perspective follows from identifying a classical geometric description of position in Fermi or Riemann normal co-ordinates with an equivalent representation of a corresponding ket vector in Hilbert space. Suppose that $x^\mu = (\tau, \boldsymbol{x}(\tau))$ refers to the normal co-ordinate system and $\bar{e}^{\hat{\mu}}{}_\nu = \delta^\mu{}_\nu + \tilde{R}^\mu{}_\nu$ is the orthonormal tetrad, such that hatted indices refer to a local Lorentz frame coinciding with the tangent space, and $\tilde{R}^\mu{}_\nu$ is a two-indexed space-time curvature dependent contribution, not to be confused with the Ricci tensor. Given that $g_{\mu\nu} = \eta_{\hat{\alpha}\hat{\beta}}\,\bar{e}^{\hat{\alpha}}{}_\mu\,\bar{e}^{\hat{\beta}}{}_\nu \approx \eta_{\mu\nu} + 2\tilde{R}_{(\mu\nu)}$, it is straightforward to determine that [15]

$${}^F\tilde{R}^\mu{}_\nu = \left[\frac{1}{2}\,{}^F R^\mu{}_{lm0}(\tau)\,\delta^0{}_\nu + \frac{1}{6}\,{}^F R^\mu{}_{lmk}(\tau)\,\delta^k{}_\nu\right]\delta x^l\,\delta x^m \tag{1}$$

in Fermi normal co-ordinates, while

$${}^R\tilde{R}^\mu{}_\nu = \frac{1}{6}\,{}^R R^\mu{}_{\alpha\beta\nu}(\tau)\,\delta x^\alpha\,\delta x^\beta \tag{2}$$

is its counterpart in Riemann normal co-ordinates, where $R^\mu{}_{\alpha\beta\nu}(\tau)$ is the local expression for the Riemann tensor, and δx^μ is interpreted as a space-time quantum fluctuation with $|\delta x^\mu| \ll |x^\mu|$ to ensure that $\tilde{R}^\mu{}_\nu \ll \delta^\mu{}_\nu$.

Suppose now that $|x^\mu\rangle = |(\tau, \boldsymbol{x})\rangle$ defines the position ket vector for normal co-ordinates. Then, from noting that $\boldsymbol{X}^{\hat{\mu}}_{(\mathrm{G})}(\tau, \boldsymbol{x}) = \bar{e}^{\hat{\mu}}{}_\nu\,x^\nu$ with $\eta_{\hat{\alpha}\hat{\beta}}\,\boldsymbol{X}^{\hat{\alpha}}_{(\mathrm{G})}\,\boldsymbol{X}^{\hat{\beta}}_{(\mathrm{G})} = g_{\mu\nu}\,x^\mu\,x^\nu$, it is possible to identify an expression [5] for the position ket vector in a local Lorentz frame as $|\boldsymbol{X}^{\hat{\mu}}_{(\mathrm{G})}(\tau, \boldsymbol{x})\rangle = \left|\bar{e}^{\hat{\mu}}{}_\nu\,x^\nu\right\rangle = U_{\mathrm{Proj.}}(\tau, \boldsymbol{x})\,|x^\mu\rangle$, where

$$U_{\mathrm{Proj.}}(\tau, \boldsymbol{x}) = 1 + \tilde{R}^\beta{}_\alpha\,\boldsymbol{x}^\alpha\,\boldsymbol{\nabla}_\beta \;=\; 1 + \frac{i}{\hbar}\,\tilde{R}_{\beta\alpha}\,\boldsymbol{x}^\alpha\,\boldsymbol{p}^\beta \tag{3}$$

is an operator to project local space-time curvature onto a local tangent space, in terms of position and canonical momentum operators $\boldsymbol{x}^\alpha$ and $\boldsymbol{p}^\alpha$. By transforming the position ket vector defined within the curved space-time background into an equivalent expression within the local Lorentz frame, it is possible to incorporate local gravitational effects "G" within a standard Hilbert space setting in flat space-time for each instance of τ, thereby allowing the standard tools of Feynman path integration to become available for future use. A schematic representation of this operation is displayed in Figure 1.

The next step is to determine the local time translation operator when applied to $|\boldsymbol{X}^{\hat{\mu}}_{(\mathrm{G})}(\tau, \boldsymbol{x})\rangle$ on the local tangent space. By analogy with the geometric description of Lie transport involving $\tau \to \tau + \Delta\tau$ [12], the transformed position ket vector is denoted by

$$\begin{aligned} \left|\boldsymbol{X}'^{\hat{\mu}}_{(\mathrm{G})}\left(\tau + \Delta\tau, \boldsymbol{x} + \Delta\boldsymbol{x}\right)\right\rangle &= \left|\boldsymbol{X}^{\hat{\mu}}_{(\mathrm{G})}\left(\tau + \Delta\tau, \boldsymbol{x} + \Delta\boldsymbol{x}\right) - \Delta\tau\left[\left(\mathcal{L}_{\boldsymbol{\xi}}\boldsymbol{X}\right)^{\hat{\mu}}(\tau, \boldsymbol{x})\right]\right\rangle \\ &= \left|\boldsymbol{X}^{\hat{\mu}}_{(\mathrm{G})}\left(\tau + \Delta\tau, \boldsymbol{x} + \Delta\boldsymbol{x}\right)\right\rangle - \frac{i}{\hbar}\,\Delta\tau\left(\mathcal{L}_{\boldsymbol{\xi}}\boldsymbol{X}\right)^{\hat{\nu}}\boldsymbol{P}_{\hat{\nu}}\,|\boldsymbol{X}^{\hat{\mu}}_{(\mathrm{G})}(\tau, \boldsymbol{x})\rangle, \end{aligned} \tag{4}$$

where $(\mathcal{L}_{\boldsymbol{\xi}}\boldsymbol{X})^{\hat{\mu}} = \xi^{\hat{\nu}}(\nabla_{\hat{\nu}}\boldsymbol{X}^{\hat{\mu}}) - \boldsymbol{X}^{\hat{\nu}}(\nabla_{\hat{\nu}}\boldsymbol{\xi}^{\hat{\mu}})$ is the Lie derivative along some vector field $\boldsymbol{\xi}^{\hat{\alpha}}$ tangent to the reference worldline, as shown in Figure 1, $\left|\boldsymbol{X}^{\hat{\mu}}_{(\mathrm{G})}\left(\tau + \Delta\tau, \boldsymbol{x} + \Delta\boldsymbol{x}\right)\right\rangle = \left|\left[\bar{e}^{\hat{\mu}}{}_{\nu}(x^{\alpha} + \Delta x^{\alpha})\right](x^{\nu} + \Delta x^{\nu})\right\rangle$, and $\boldsymbol{P}^{\hat{\alpha}}$ is the canonical momentum operator in local Lorentz frame co-ordinates. To demonstrate path integral invariance under reparametrization of τ, allow for $(\mathcal{L}_{\boldsymbol{\xi}}\boldsymbol{X})^{\hat{\mu}} \to V^0\,(\mathcal{L}_{\boldsymbol{\xi}}\boldsymbol{X})^{\hat{\mu}}$, where V^0 is the time component of the four-vector $V^{\mu} = \Delta x^{\mu}/\Delta\tau$, and serves as the lapse function. Obviously, τ is the proper time when $V^0 = 1$.

For what follows, assume that all indices are unhatted and refer to local Lorentz frame co-ordinates. By making use of (3), it follows that

$$\left|\boldsymbol{X}'^{\mu}_{(\mathrm{G})}\left(\tau + \Delta\tau, \boldsymbol{x} + \Delta\boldsymbol{x}\right)\right\rangle = U_{\Delta\tau}(V^{\alpha}, \boldsymbol{\xi}^{\alpha})\,|\boldsymbol{X}^{\mu}_{(\mathrm{G})}(\tau, \boldsymbol{x})\rangle, \tag{5}$$

where

$$\begin{aligned} U_{\Delta\tau}(V^{\alpha}, \boldsymbol{\xi}^{\alpha}) = 1 - \frac{i}{\hbar}\,V^0\,\Delta\tau\Bigg\{&\left[\delta^0{}_{\alpha} - \mathcal{F}(\tilde{R})_{\alpha\beta}\,\frac{V^{\beta}}{V^0} + (\mathcal{L}_{\boldsymbol{\xi}}\boldsymbol{X})_{\alpha}\right] \\ &+ \frac{i}{\hbar}\,\eta_{\alpha\beta}\,\tilde{R}_{\lambda\sigma}\,x^{\sigma}\,\frac{V^{\beta}}{V^0}\,\boldsymbol{P}^{\lambda}\Bigg\}\,\boldsymbol{P}^{\alpha} \end{aligned} \tag{6}$$

is the infinitesimal local time translation operator, and

$$\begin{aligned} \mathcal{F}(\tilde{R})_{\alpha\beta} = &\left(\tilde{R}_{\alpha\beta,\mu} + \frac{1}{2!}\,\tilde{R}_{\alpha\sigma,\beta\mu}\,x^{\sigma}\right)\Delta x^{\mu} \\ &+ \left(\frac{1}{2!}\,\tilde{R}_{\alpha\beta,\mu\nu} + \frac{1}{3!}\,\tilde{R}_{\alpha\sigma,\beta\mu\nu}\,x^{\sigma}\right)\Delta x^{\mu}\,\Delta x^{\nu} + O\left((\Delta x)^3\right). \end{aligned} \tag{7}$$

It should be noted that

$$U^{-1}_{\Delta\tau}(V^{\alpha}, \boldsymbol{\xi}^{\alpha}) = U_{-\Delta\tau}(V^{\alpha}, \boldsymbol{\xi}^{\alpha}) \;\neq\; U^{\dagger}_{\Delta\tau}(V^{\alpha}, \boldsymbol{\xi}^{\alpha}). \tag{8}$$

The fact that (6) does not satisfy unitarity is not particularly surprising, since it is well-known from spin-1/2 particle quantum mechanics in curved spacetime that the respective Dirac Hamiltonian is not strictly Hermitian [16,17].

At the same time, the explicit coupling of $\hbar$ with space-time curvature, as found in the last term in (6), has unexpected and important implications, namely the demonstration of quantum mechanical weak equivalence principle violation, as shown later in this Letter.

3 Configuration Space Path Integral in Curved Space-Time

3.1 Formal Expression for the Path Integral

Having now obtained (6), it is relatively straightforward to determine the configuration space path integral, though with some subtle new features. Adopting the Heisenberg representation [5] for the initial and final position ket vectors $\left|\boldsymbol{X}^{(\mathrm{G})}_{(\mathrm{i})}(\tau_\mathrm{i}, \boldsymbol{x}_\mathrm{i})\right\rangle$ and $\left|\boldsymbol{X}'^{(\mathrm{G})}_{(\mathrm{f})}(\tau_\mathrm{f}, \boldsymbol{x}_\mathrm{f})\right\rangle = U^{-1}_{(\tau_\mathrm{f}-\tau_\mathrm{i})}(V^\alpha, \boldsymbol{\xi}^\alpha)\left|\boldsymbol{X}^{(\mathrm{G})}_{(\mathrm{f})}(\tau_\mathrm{i}, \boldsymbol{x}_\mathrm{i})\right\rangle$, let $\tau_\mathrm{f} - \tau_\mathrm{i} = N\Delta\tau$ for integer N, such that the scalar particle propagator can be written as

$$\begin{aligned}\left\langle \boldsymbol{X}'^{(\mathrm{G})}_{(\mathrm{f})}(\tau_\mathrm{f}, \boldsymbol{x}_\mathrm{f}) \,\middle|\, \boldsymbol{X}^{(\mathrm{G})}_{(\mathrm{i})}(\tau_\mathrm{i}, \boldsymbol{x}_\mathrm{i})\right\rangle &= \left\langle \boldsymbol{X}^{(\mathrm{G})}_{(\mathrm{f})}(\tau_\mathrm{i}, \boldsymbol{x}_\mathrm{i}) \left| U^{-1\dagger}_{N\Delta\tau} \right| \boldsymbol{X}^{(\mathrm{G})}_{(\mathrm{i})}(\tau_\mathrm{i}, \boldsymbol{x}_\mathrm{i})\right\rangle \\ = \left\langle \boldsymbol{X}^{(\mathrm{G})}_{(\mathrm{f})}(\tau_\mathrm{i}, \boldsymbol{x}_\mathrm{i}) \right| &\left(\prod_{n=1}^{N} \mathbf{1}_{(n)}\, U^{-1\dagger}_{\Delta\tau}\right) \mathbf{1}_{(0)} \left| \boldsymbol{X}^{(\mathrm{G})}_{(\mathrm{i})}(\tau_\mathrm{i}, \boldsymbol{x}_\mathrm{i})\right\rangle , \end{aligned} \tag{9}$$

where

$$\mathbf{1}_{(n)} = \int_{-\infty}^{\infty} \mathrm{d}^3\boldsymbol{X}_{(n)} \left|\boldsymbol{X}_{(n)}(\tau_n, \boldsymbol{x}_n)\right\rangle \left\langle \boldsymbol{X}_{(n)}(\tau_n, \boldsymbol{x}_n)\right| \tag{10}$$

is defined in terms of strictly flat space-time position ket vectors. The two extra identity operators $\mathbf{1}_{(0)}$ and $\mathbf{1}_{(N)}$ are inserted in order to determine that, to leading order in curvature,

$$\begin{aligned}\left\langle \boldsymbol{X}_{(0)} \middle| \boldsymbol{X}^{(\mathrm{G})}_{(\mathrm{i})}(\tau_\mathrm{i}, \boldsymbol{x}_\mathrm{i})\right\rangle &= \int_{-\infty}^{\infty} \frac{\mathrm{d}^3\boldsymbol{P}_{(0)}}{(2\pi\hbar)^3}\left[1 + \frac{i}{\hbar}\tilde{R}_{ij}(\tau_\mathrm{i}, \boldsymbol{x}_\mathrm{i})\boldsymbol{X}^j_{(\mathrm{i})}\,\boldsymbol{P}^i_{(0)}\right] \\ &\qquad\times \exp\left[\frac{i}{\hbar}\left(\boldsymbol{X}_{(0)} - \boldsymbol{X}_{(\mathrm{i})}\right)\cdot \boldsymbol{P}_{(0)}\right] \\ &\approx \delta^3\left(\boldsymbol{X}_{(0)} - \left[\boldsymbol{X}_{(\mathrm{i})} - \tilde{R}_{ij}(\tau_\mathrm{i}, \boldsymbol{x}_\mathrm{i})\boldsymbol{X}^j_{(\mathrm{i})}\,\hat{\boldsymbol{x}}^i\right]\right), \end{aligned} \tag{11}$$

$$\left\langle \boldsymbol{X}^{(\mathrm{G})}_{(\mathrm{f})}(\tau_\mathrm{i}, \boldsymbol{x}_\mathrm{i}) \middle| \boldsymbol{X}_{(N)}\right\rangle \approx \delta^3\left(\boldsymbol{X}_{(N)} - \left[\boldsymbol{X}_{(\mathrm{f})} - \tilde{R}_{ij}(\tau_\mathrm{i}, \boldsymbol{x}_\mathrm{i})\boldsymbol{X}^j_{(\mathrm{f})}\,\hat{\boldsymbol{x}}^i\right]\right). \tag{12}$$

Given that the Hamiltonian for a free scalar particle is $H(\boldsymbol{P}) = \sqrt{\boldsymbol{P}\cdot\boldsymbol{P} + m^2}$, it is possible to integrate out the intermediate momentum states exactly to first-order in $\tilde{R}_{\mu\nu}$. This is accomplished by employing the integral representation of the modified Bessel function [11,18]

$$K_{\pm\nu}\,(\mu\beta) = \frac{\beta^{-\nu}}{2}\, e^{-i\nu\pi/2} \int\limits_0^\infty \mathrm{d}N\, N^{\nu-1}\, \exp\left[\frac{i\,\mu}{2}\left(N - \frac{\beta^2}{N}\right)\right] , \tag{13}$$

for $\nu = 1/2$, with $\mathrm{Im}(\mu) > 0$ and $\mathrm{Im}(\mu\beta^2) < 0$. Assuming that $\mathrm{Im}(\Delta\tau) \lesssim 0$ and identifying

$$\mu = -\frac{V^0\,\Delta\tau}{\lambdabar}\,, \tag{14}$$

$$\begin{aligned}\beta = {} & -\frac{i}{m}\left[1 - \mathcal{G}(\tilde{R})_{0\alpha}\,\frac{V^\alpha}{V^0} + (\mathcal{L}_{\boldsymbol{\xi}}\boldsymbol{X})_0 + \frac{i}{\hbar}\left(\tilde{R}_{0\alpha}\,x^\alpha\,\frac{V_j}{V^0} - \tilde{R}_{j\alpha}\,x^\alpha\right)\boldsymbol{P}^j\right] \\ & \times\sqrt{\boldsymbol{P}\cdot\boldsymbol{P} + m^2}\,,\end{aligned} \tag{15}$$

where

$$\mathcal{G}(\tilde{R})_{\mu\nu} = \mathcal{F}(\tilde{R})_{\mu\nu} + \tilde{R}_{\mu\nu} + \tilde{R}_{\mu\alpha,\nu}\,x^\alpha + (\tilde{R}^\alpha{}_\alpha)\,\eta_{\mu\nu}\,, \tag{16}$$

and $\lambdabar = \hbar/m$ is the scalar particle's reduced Compton wavelength, (9) can be recast into Gaussian form with respect to integration over $\boldsymbol{P}_{(n)}$ at local time $\tau_{(n)}$.

Much of the relevant details for computing the free-particle scalar propagator are deferred to the forthcoming longer publication [13]. However, it is relatively straightforward to demonstrate that when $V^0\Delta\tau \to \mathrm{d}\tau$, $(V^0\Delta\tau)^{-1} \to \delta(0)$, and $V^\mu/V^0 \to \dot{x}^\mu(\tau) = (1, \dot{\boldsymbol{x}}(\tau))$, the integration measure for the skeletonized path integral becomes

$$\lim_{N\to\infty}\left(\frac{1}{2\pi\lambdabar\, i\, V^0\Delta\tau}\right)^{3N/2}\prod_{n=0}^{N}\int\limits_{-\infty}^{\infty}\mathrm{d}^3\boldsymbol{X}_{(n)} \to \int\mathcal{D}\left[\boldsymbol{X}(\tau)\right]\,, \tag{17}$$

and the configuration space propagator in curved space-time becomes

$$\begin{aligned}\left\langle \boldsymbol{X}'^{(\mathrm{G})}_{(\mathrm{f})}(\tau_{\mathrm{f}}, \boldsymbol{x}_{\mathrm{f}}) \,\middle|\, \boldsymbol{X}^{(\mathrm{G})}_{(\mathrm{i})}(\tau_{\mathrm{i}}, \boldsymbol{x}_{\mathrm{i}})\right\rangle \; = \; & \int\mathcal{D}\left[\boldsymbol{X}(\tau)\right]\exp\left[\frac{i}{\hbar}\int\limits_{\tau_{\mathrm{i}}}^{\tau_{\mathrm{f}}}\mathrm{d}\tau\, L^{(\mathrm{G})}_{(\mathrm{Re},0)}\right] \\ \times\exp\left[\frac{i}{\hbar}\int\limits_{\tau_{\mathrm{i}}}^{\tau_{\mathrm{f}}}\mathrm{d}\tau\left(L^{(\mathrm{G})}_{(\mathrm{Re},1)} + i\left[L^{(\mathrm{G})}_{(\mathrm{Im},0)} + \lambdabar\,\delta(0)\,L^{(\mathrm{G})}_{(\mathrm{Im},1)}\right]\right)\right]\,, &\end{aligned} \tag{18}$$

where the free-particle Lagrangian $L^{(\mathrm{G})}(\tau, \boldsymbol{x}(\tau), \dot{\boldsymbol{x}}(\tau)) = L^{(\mathrm{G})}_{(\mathrm{Re},0)} + L^{(\mathrm{G})}_{(\mathrm{Re},1)} + i\left[L^{(\mathrm{G})}_{(\mathrm{Im},0)} + ƛ\,\delta(0)\,L^{(\mathrm{G})}_{(\mathrm{Im},1)}\right]$ is expressed in terms of

$$\begin{aligned} L^{(\mathrm{G})}_{(\mathrm{Re},0)} &= -m\left[1 - \frac{1}{2}\left\{2\,\mathcal{G}(\tilde{R})_{(00)} + 4\,\mathcal{G}(\tilde{R})_{(0j)}\,\dot{x}^j + \left[\eta_{ij} + 2\,\mathcal{G}(\tilde{R})_{(ij)}\right]\dot{x}^i\,\dot{x}^j\right\}\right] \\ &\approx -m\left[-g^{(\mathrm{eff.})}_{\mu\nu}\,\dot{x}^\mu\,\dot{x}^\nu\right]^{1/2}, \qquad g^{(\mathrm{eff.})}_{\mu\nu} \; = \; \eta_{\mu\nu} + 2\,\mathcal{G}(\tilde{R})_{(\mu\nu)}\,, \end{aligned} \tag{19}$$

the expected free-particle Lagrangian in curved space-time that generates the geodesic equation, along with

$$L^{(\mathrm{G})}_{(\mathrm{Re},1)} = -m\left\{(\mathcal{L}_{\boldsymbol{\xi}}\boldsymbol{X})_\mu + 2\left[(\mathcal{L}_{\boldsymbol{\xi}}\boldsymbol{X})_0\,\delta^0{}_\mu - \mathcal{G}(\tilde{R})_{0\mu}\right]\eta_{ij}\,\dot{x}^i\,\dot{x}^j\right\}\dot{x}^\mu\,, \tag{20}$$

$$\begin{aligned} L^{(\mathrm{G})}_{(\mathrm{Im},0)} &= m\left\{ƛ\left[(\mathcal{L}_{\boldsymbol{\xi}}\boldsymbol{X})^\alpha{}_{,\alpha} - \mathcal{H}(\tilde{R})_\alpha\,\dot{x}^\alpha\right] + \frac{1}{2ƛ}\,\tilde{R}_{k\alpha}\,x^\alpha\,\dot{x}^k\left(1 - 3\,\eta_{ij}\,\dot{x}^i\,\dot{x}^j\right)\right. \\ &\qquad \left. - \frac{1}{ƛ}\,\tilde{R}_{0\alpha}\,x^\alpha\left(1 - 3\,\eta_{ij}\,\dot{x}^i\,\dot{x}^j\right)\left(1 - \eta_{kl}\,\dot{x}^k\,\dot{x}^l\right)\right\}, \end{aligned} \tag{21}$$

$$\begin{aligned} L^{(\mathrm{G})}_{(\mathrm{Im},1)} &= m\left\{\frac{3}{2}\left[(\mathcal{L}_{\boldsymbol{\xi}}\boldsymbol{X})_0 - \mathcal{G}(\tilde{R})_{00}\right] + \frac{5}{2}\left[(\mathcal{L}_{\boldsymbol{\xi}}\boldsymbol{X})_j - \mathcal{G}(\tilde{R})_{j0}\right]\dot{x}^j\right. \\ &\qquad \left. - \frac{5}{4}\left[\eta_{ij} + 2\,\mathcal{G}(\tilde{R})_{(ij)}\right]\dot{x}^i\,\dot{x}^j + \left[(\mathcal{L}_{\boldsymbol{\xi}}\boldsymbol{X})_0 - \mathcal{G}(\tilde{R})_{0\mu}\,\dot{x}^\mu\right]\eta_{ij}\,\dot{x}^i\,\dot{x}^j\right\}, \end{aligned} \tag{22}$$

where

$$\mathcal{H}(\tilde{R})_\mu = \mathcal{F}(\tilde{R})^\alpha{}_{\mu,\alpha} + \tilde{R}^\alpha{}_{\alpha,\mu}\,, \tag{23}$$

and

$$\boldsymbol{X}^{(\mathrm{G})}(\tau_{(\mathrm{i,f})}) = \boldsymbol{X}(\tau_{(\mathrm{i,f})}) - \tilde{R}_{ij}(\tau_{\mathrm{i}}, \boldsymbol{x}_{\mathrm{i}})\,\boldsymbol{X}^j(\tau_{(\mathrm{i,f})})\,\hat{\boldsymbol{x}}^i \tag{24}$$

from (11) and (12) in the continuum limit.

3.2 Physical Consequences

Even at a purely formal level, there are some valuable insights to be gained from a preliminary analysis of (18). First, it contains the correct free-particle Lagrangian (19) in the weak-field limit, with additional terms in (20) that both preserve the conservation of probability and satisfy the weak equivalence principle. In contrast, all the probability violating contributions due to curvature, namely (21) and (22), show a direct coupling of ƛ with the gravitational background, yielding a *quantum violation* of the weak equivalence principle at the Compton wavelength scale.

The fact that *only* the probability non-conserving terms in the scalar propagator are responsible for weak equivalence principle violation is especially interesting and deserves careful analysis. In particular, it is straightforward to see that, under the interchange of $\tau_{\rm i} \leftrightarrow \tau_{\rm f}$ and primed-to-unprimed ket vector notation in (18) followed by taking its Hermitian conjugate, the transformed scalar propagator now reveals the existence of a time reversal symmetry breakdown, precisely due to (21) and (22). This observation may provide a potentially satisfactory reason for why there exists a macroscopic preference for time to propagate in the forward direction only. Given that there is already some potential evidence for weak equivalence principle violation at the Compton wavelength scale in the context of spin-1/2 particle propagation in curved space-time [17], this particular observation gained from (18) is worthy of future exploration.

4 Regularization of the Path Integral

4.1 Cartesian Co-ordinates

Explicit evaluation of (18) in skeletonized form is a straightforward exercise involving multiple Gaussian integrations with respect to $\prod_{n=1}^{N-1} {\rm d}^3\boldsymbol{X}_{(n)}$. However, it is necessary to then regularize the propagator in order to remove all of its singular contributions in the limit as $V^0 \to 0$. Normally, this involves describing (18) according to the ansatz

$$\begin{aligned} \left\langle \boldsymbol{X}'^{({\rm G})}_{({\rm f})}(\tau_{\rm f}, \boldsymbol{x}_{\rm f}) \,\middle|\, \boldsymbol{X}^{({\rm G})}_{({\rm i})}(\tau_{\rm i}, \boldsymbol{x}_{\rm i}) \right\rangle_{({\rm reg.})} \; &\equiv \; \left(\frac{1}{2\pi \bar{\lambda}\, i\, V^0 \, (\tau_{\rm f} - \tau_{\rm i})} \right)^{3/2} \\ \times \; \exp\left[\frac{i}{2} \, \frac{m}{\hbar} \, \frac{\left(\eta_{\mu\nu} \, \Delta\boldsymbol{X}^\mu_{({\rm i}\to{\rm f})} \, \Delta\boldsymbol{X}^\nu_{({\rm i}\to{\rm f})} \right)}{V^0 \, (\tau_{\rm f} - \tau_{\rm i})} \right] & \sum_{k=0}^\infty a_k(x^\mu_{\rm i}, x^\mu_{\rm f}) \left(i \, V^0 \right)^k \, , \qquad (25) \end{aligned}$$

where $\Delta\boldsymbol{X}^\mu_{({\rm i}\to{\rm f})} = \boldsymbol{X}^\mu_{({\rm f})} - \boldsymbol{X}^\mu_{({\rm i})}$ and $a_k(x^\mu_{\rm i}, x^\mu_{\rm f})$ are the curvature-dependent Seeley-DeWitt coefficients [3,8,19], whose values are determined from solving the heat kernel equation. For (18) in skeletonized form, it so happens that it is unnecessary to perform this calculation to achieve this objective, since the propagator prior to the Gaussian integrations can easily be put into power series form consistent with (25), such that all inverse powers of V^0 are identified by inspection alone and subsequently removed by hand.

While the relevant details of this computation are deferred to the aforementioned longer publication [13], it follows that the regularized scalar particle propagator is

$$
\begin{aligned}
&\left\langle \boldsymbol{X}'^{(\mathrm{G})}_{(\mathrm{f})}(\tau_\mathrm{f},\boldsymbol{x}_\mathrm{f}) \,\middle|\, \boldsymbol{X}^{(\mathrm{G})}_{(\mathrm{i})}(\tau_\mathrm{i},\boldsymbol{x}_\mathrm{i}) \right\rangle_{(\mathrm{reg.})} = \\
&\lim_{N\to\infty} \left(\frac{1}{2\pi\lambdabar\, i\, V^0\,(\tau_\mathrm{f}-\tau_\mathrm{i})}\right)^{3/2} \exp\left[\frac{i}{2}\,\frac{m}{\hbar}\,\frac{\left(\eta_{\mu\nu}\,\Delta\boldsymbol{X}^\mu_{(\mathrm{i}\to\mathrm{f})}\,\Delta\boldsymbol{X}^\nu_{(\mathrm{i}\to\mathrm{f})}\right)}{V^0\,(\tau_\mathrm{f}-\tau_\mathrm{i})}\right] \\
&\times \sum_{k=0}^{\infty}\sum_{n=1}^{N}\frac{1}{k!}\left\{\left[C^{(k,0)}_{(n)}(x^\mu) + \sum_{l=1}^{4}\frac{k!}{(k+l)!}\left(\frac{-i}{2N}\right)^l \frac{C^{(k+l,l)}_{(n)}(x^\mu)}{\lambdabar^l}\right]\right. \\
&\left. + \exp\left[\frac{n}{N}\,\Delta\boldsymbol{X}^\alpha_{(\mathrm{i}\to\mathrm{f})}\,\frac{\partial}{\partial x^\alpha}\right]\left[C^{(k,0)}_{(\mathcal{L},n)}(x^\mu) + \sum_{l=1}^{2}\frac{k!}{(k+l)!}\left(\frac{-i}{2N}\right)^l \frac{C^{(k+l,l)}_{(\mathcal{L},n)}(x^\mu)}{\lambdabar^l}\right]\right\} \\
&\times \left(\frac{-i\,V^0\,\Delta\tau}{2\lambdabar}\right)^k \exp\left[-i\,\frac{m}{\hbar}\left(\frac{\tilde{R}_{(ij)}(\tau_\mathrm{i},\boldsymbol{x}_\mathrm{i})\,\Delta\boldsymbol{X}^i_{(\mathrm{i}\to\mathrm{f})}\,\Delta\boldsymbol{X}^j_{(\mathrm{i}\to\mathrm{f})}}{V^0\,(\tau_\mathrm{f}-\tau_\mathrm{i})}\right)\right] , \qquad (26)
\end{aligned}
$$

where $N\Delta\tau = \tau_\mathrm{f} - \tau_\mathrm{i} \equiv 1$ and, to leading-order in curvature, the coefficients $C^{(k,l)}_{(n)}(x^\mu)$ and $C^{(k,l)}_{(\mathcal{L},n)}(x^\mu)$—the latter of which are proportional to $(\mathcal{L}_{\boldsymbol{\xi}}\boldsymbol{X})^\mu(\tau_\mathrm{i},\boldsymbol{x}_\mathrm{i})$—are generally *complex-valued*. Again, only the probability non-conserving imaginary parts denote a quantum violation of the weak equivalence principle via the explicit coupling of m to the gravitational background, as evidenced in the case of $l = 0$, where

$$
\begin{aligned}
C^{(k,0)}_{(n)}(x^\mu) &= 1 - \left(2k - \frac{3}{2}\right)\mathcal{G}(\tilde{R})_{00} + 2i\,k\left(\lambdabar\,\mathcal{H}(\tilde{R})_0 + \frac{1}{\lambdabar}\,\tilde{R}_{00}\,\tau_{(n)}\right. \\
&\qquad \left. + \frac{1}{\lambdabar}\,\tilde{R}_{0j}\left[\boldsymbol{X}^j_{(\mathrm{i})} + \frac{n}{N}\,\Delta\boldsymbol{X}^j_{(\mathrm{i}\to\mathrm{f})}\right]\right) , \qquad (27) \\
C^{(k,0)}_{(\mathcal{L},n)}(x^\mu) &= \left(2k - \frac{3}{2}\right)(\mathcal{L}_{\boldsymbol{\xi}}\boldsymbol{X})_0(\tau_\mathrm{i},\boldsymbol{x}_\mathrm{i}) - 2i\,k\,\lambdabar\,(\mathcal{L}_{\boldsymbol{\xi}}\boldsymbol{X})^\alpha{}_{,\alpha}(\tau_\mathrm{i},\boldsymbol{x}_\mathrm{i}) \,. \qquad (28)
\end{aligned}
$$

In addition to these new physical predictions, there also emerges the prediction of a curvature-dependent and *gauge-invariant* overall phase factor in the propagator, as found in the final line of (26), that is dependent upon the spatial separation between the initial and final position states. This phase factor can be interpreted as a manifestation of the gravitational Aharonov-Bohm effect [20–24] and Berry's phase [25–27], each of which are the subjects of extensive study already. Such an effect to come from the path integral should reveal important consequences that are also worthy of future consideration.

4.2 Curvilinear Co-ordinates

It is also straightforward to evaluate (18) in terms of curvilinear co-ordinates, following the established techniques first put forward by Kleinert [3,4]. This is done by letting $\boldsymbol{X}^\mu(\tau, \boldsymbol{x}) = \boldsymbol{X}^\mu(\tau, \boldsymbol{x}(q))$, where q are the generalized spatial curvilinear co-ordinates. Following Kleinert's treatment of the integration measure $\prod_{n=1}^{N-1} \mathrm{d}^3 \boldsymbol{X}_{(n)} \to \prod_{n=1}^{N-1} \mathrm{d}^3(\Delta \boldsymbol{X}_{(n)})$ to integrate over $\Delta \boldsymbol{X}^j_{(n)}$ in terms of the pre-point description of $\boldsymbol{X}^j_{(n)} = \boldsymbol{X}^j_{(n-1)} + \Delta \boldsymbol{X}^j_{(n)} = \boldsymbol{X}^j_{(0)} + \sum_{k=1}^n \Delta \boldsymbol{X}^j_{(k)}$, it follows that $\mathrm{d}^3(\Delta \boldsymbol{X}_{(n)}) \to \mathrm{d}^3(\Delta q_{(n)})\, J(q_{(n)})$, where $J(q_{(n)})$ is the Jacobian expressed in terms of the affine connection $\hat{\Gamma}^i{}_{jk}(\tau_{(n)})$ which satisfies the geodesic equation [3,4]

$$\frac{\mathrm{d}^2 q^i_{(n)}}{\mathrm{d}\tau^2} + \hat{\Gamma}^i{}_{jk}(\tau_{(n)}) \, \frac{\mathrm{d}q^j_{(n)}}{\mathrm{d}\tau} \, \frac{\mathrm{d}q^k_{(n)}}{\mathrm{d}\tau} = 0 \tag{29}$$

for spatial curvature in the absence of torsion. This ensures that the short-time action to connect infinitesimally separated events in space-time describes classical motion in the presence of a locally curved background.

Again, with more details to be shown in the longer publication [13], it is determined that the regularized scalar particle propagator in curvilinear co-ordinates takes the form

$$\begin{aligned}
&\Big\langle \boldsymbol{X}'^{(\mathrm{G})}_{(\mathrm{f})}(\tau_\mathrm{f}, \boldsymbol{x}_\mathrm{f}) \,\Big|\, \boldsymbol{X}^{(\mathrm{G})}_{(\mathrm{i})}(\tau_\mathrm{i}, \boldsymbol{x}_\mathrm{i}) \Big\rangle_{(\mathrm{reg.})} \;= \\
&\lim_{N\to\infty} \exp\left[-\frac{i}{2}\,\frac{N\,\Delta\tau}{\bar{\lambda}\,V^0}\right] \exp\left[\Big(i\,\bar{\lambda}\,V^0\,\Delta\tau\Big) \sum_{s=1}^{N-1} \mathcal{N}_{(0)}(\hat{\Gamma}_{(s)})\right] \\
&\times \left(\frac{1}{2\pi\bar{\lambda}\,i\,V^0\,\Delta\tau}\right)^{3/2} \exp\left[\frac{i}{2}\,\frac{m}{\hbar}\,\frac{\Big(\eta_{ij}\,\Delta\boldsymbol{X}^\mu_{(N)}\,\Delta\boldsymbol{X}^\nu_{(N)}\Big)}{V^0\,\Delta\tau}\right] \\
&\times \sum_{k=0}^{\infty}\sum_{n=1}^{N} \frac{1}{k!} \Bigg\{ \Bigg[\Big\langle C^{(k,0)}_{(n)}(x^\mu) \Big\rangle + \sum_{l=1}^{4} \frac{k!}{(k+l)!} \left(\frac{-i}{2N}\right)^l \frac{\Big\langle C^{(k+l,l)}_{(n)}(x^\mu) \Big\rangle}{\bar{\lambda}^l} \Bigg] \\
&+ \exp\left[N\,\Delta\tau\,\frac{\partial}{\partial\tau}\right] \exp\left[\Delta\boldsymbol{X}^j_{(N)}\,\frac{\partial}{\partial x^j}\right] \exp\Bigg[\Big(i\,\bar{\lambda}\,V^0\,\Delta\tau\Big) \Bigg\{ \frac{1}{2}\,\bar{h}^{ab}\,\frac{\partial}{\partial q^a}\,\frac{\partial}{\partial q^b} \\
&+ \sum_{s=1}^{N-1} \Bigg[\mathcal{N}^a_{(\mathcal{L},1)}(\hat{\Gamma}_{(s)})\,\frac{\partial}{\partial q^a} + \Big(i\,\bar{\lambda}\,V^0\,\Delta\tau\Big)\,\mathcal{N}^{ab}_{(\mathcal{L},2)}(\hat{\Gamma}_{(s)})\,\frac{\partial}{\partial q^a}\,\frac{\partial}{\partial q^b} \\
&+ \; \Big(i\,\bar{\lambda}\,V^0\,\Delta\tau\Big)^2\,\mathcal{N}^{abcd}_{(\mathcal{L},4)}(\hat{\Gamma}_{(s)})\,\frac{\partial}{\partial q^a}\,\frac{\partial}{\partial q^b}\,\frac{\partial}{\partial q^c}\,\frac{\partial}{\partial q^d} \Bigg] \Bigg\} \Bigg] \; \Big[\Big\langle C^{(k,0)}_{(\mathcal{L},n)}(x^\mu) \Big\rangle
\end{aligned}$$

$$+ \sum_{l=1}^{2} \frac{k!}{(k+l)!} \left(\frac{-i}{2N}\right)^{l} \frac{\left\langle C^{(k+l,l)}_{(\mathcal{L},n)}(x^{\mu}) \right\rangle}{\lambdabar^{l}} \Bigg] \Bigg\} \left(\frac{-i\, V^{0}\, \Delta\tau}{2\lambdabar}\right)^{k} , \tag{30}$$

where $\bar{h}^{ab} = \eta^{ij}\,(\partial q^a/\partial x^i)\,(\partial q^b/\partial x^j)$ is the inverse of the induced metric $h_{ab} = \eta_{ij}\,(\partial x^i/\partial q^a)\,(\partial x^j/\partial q^b)$ in curvilinear co-ordinates, $\mathcal{N}^{abc\cdots}(\hat{\Gamma})$ is a multi-indexed function of the affine connection, and $\left\langle C^{(k,l)}(x^{\mu}) \right\rangle$ in (30) comprises of terms coupled to even powers of $\Delta\boldsymbol{X}^{j}_{(n)}$ that survive the integration over $\mathrm{d}^3(\Delta\boldsymbol{X}_{(n)})$, with $\boldsymbol{X}_{(0,N)} = \boldsymbol{X}^{(\mathrm{G})}(\tau_{(\mathrm{i,f})})$ from (24).

5 Conclusion

This Letter demonstrates a fundamentally different approach to path integral quantum mechanics in curved space-time for a scalar relativistic particle, strongly motivated by Feynman's original vision of a sum-over-histories, but in terms of propagation due to a non-unitary local time translation operator that incorporates local curvature contributions. It reveals what appear to be significant physical predictions, with potentially broad implications concerning quantum mechanical interactions in a non-trivial gravitational field.

From this approach shown above, a configuration space propagator for a particle of mass m is derived that reveals the prediction of a quantum violation of the weak equivalence principle at the Compton wavelength scale, some *twenty orders of magnitude larger* than the Planck scale if m is a subatomic particle. This indicates the significant potential for identifying fundamental relationships between quantum matter and space-time curvature that would otherwise be obscured from view by adopting a strictly unitary time translation perspective. The fact that *only* the probability non-conserving contributions to the propagator violate the weak equivalence principle suggests the prediction that time reversal symmetry is satisfied *only* at a strictly classical length scale, and that its breakdown results in a preferred arrow of time motivated by quantum mechanics alone. Furthermore, there exists the prediction of a curvature-dependent and gauge-invariant phase factor identified as the gravitational analogue of the Aharonov-Bohm effect and Berry's phase, worthy of a deeper investigation to probe its physical consequences.

It is worthwhile to consider further developments of this approach when applied to non-zero integer and half-integer spin particles [28]. The results derived from this treatment may provide the foundation for later considering a many-body particle treatment in curved space-time, ultimately leading towards an alternative approach to quantum field theory in curved space-time that may be compared with established approaches contained within the literature [8].
